MISS CHAMCHURI BUMRUNGSINMON : ONE STEP FLAME SPRAY PYROLYSIS OF NANOCRYSTALLINE AG DOPED TiO<sub>2</sub> FOR PHOTOCATALYTIC CO<sub>2</sub> REDUCTION THESIS ADVISOR : OKORN MEKASUWANDUMRONG

In this research, nanocrystalline silver (Ag) deposited on TiO<sub>2</sub> support (Ag/TiO<sub>2</sub>) photocatalysts were prepared by dry impregnation method (IM) using commercial TiO<sub>2</sub> (P25) as a support and flame spray pyrolysis (FSP) using titanium (IV) isopropoxide and silver nitrate as a Ti and Ag sources, respectively. The physiochemical properties of all photocatalyst were characterized by several techniques such as X-ray diffraction (XRD), UV-Vis spectroscopy, Photoluminescence spectrometer (PL), Transmission electron microscopy (TEM), X-ray photoelectron spectroscopy (XPS) and N<sub>2</sub>-physorption (BET). The activities of photocatalyst were studied in photocatalytic CO<sub>2</sub> reduction under UV irradiation at room temperature. The TEM result of IM-made catalyst exhibited a regular shape and well-dispersed Ag particles with the particle size around 2-3 nm. This result is similar to FSP-made catalyst. The XRD pattern of FSP-7%wt Ag/TiO<sub>2</sub> photocatalyst showed the peak positions of silver metal phase while, the peak of Ag metal of other FSP-Ag/TiO<sub>2</sub> and IM-Ag/TiO<sub>2</sub> were not observed. This could be due to the fine dispersion of Ag metal on those supports or formation of amorphous particles. Increasing of Ag doping contents on TiO<sub>2</sub> led to the decrease of the PL spectra. The band gap energy (E<sub>g</sub>) was also decreased as the Ag loading content increased. The FSP-Ag/TiO<sub>2</sub> displayed the yield of methane (umol/gCat.h) higher than pure TiO<sub>2</sub> and the IM-Ag/TiO<sub>2</sub>. The energy band gap of all Ag/TiO<sub>2</sub> was decreased by increasing Ag doped on TiO<sub>2</sub>. All Ag/TiO<sub>2</sub> photocatalysts exhibits the photoactivity higher than pure TiO<sub>2</sub>. The best activity is FSP-7%wt Ag/TiO<sub>2</sub> photocatalyst. The effect of the enhanced adsorption UV light, less recombination rate and less energy bandgap cause the highest photocatalytic activity.

## ACKNOWLEDGEMENTS

The author is really grateful for Associate Professor Okorn Mekasuwandumrong. He is support, guidance and inspiration in this thesis. Moreover, I would like to thank a chairman and the committees for your correctness and suggestion.

Furthermore, I am grateful to thank the Research and Development Institute of Silpakorn University for supporting the equipment and laboratory, the National metal and Materials Technology Center (MTEC) for Transmission electron microscopy (TEM), Center of Excellence on Catalysis and Catalytic reaction Engineering of Chulalongkorn University for X-ray diffraction (XRD), UV-Vis spectroscopy, Photoluminescence spectrometer (PL) and X-ray photoelectron spectroscopy (XPS).

# CHAPTER I

## INTRODUCTION

### 1.1 Motivation

Global warming and climate change have become one of the biggest hazards on the earth due to many causes on all living things on the planet. The primary source of greenhouse gases is carbon dioxide ( $\text{CO}_2$ ) in the atmosphere. An increase in nearly 8 ppm of  $\text{CO}_2$  has been reported for the period of 2011 to 2014 and it reached 398.55ppm in 2014 [1]. Presently, carbon dioxide ( $\text{CO}_2$ ) concentration is increased because of the burning from the consumption of waste, human activities, industrial factory and fossil fuel such as coal power plant, oil and natural gas [7-9]. The growing consumption of these reason hazardous environmental pollutions [10-13]. The conversion of carbon dioxide ( $\text{CO}_2$ ) into fuels such as carbon monoxide (CO), methane ( $\text{CH}_4$ ), methanol ( $\text{CH}_3\text{OH}$ ), formic acid ( $\text{HCOOH}$ ), formaldehyde ( $\text{HCHO}$ ) [14] and hydrogen ( $\text{H}_2$ ) has become one of most inventing technologies to reduce global warming and the energy crisis [15-17]. The technology to convert  $\text{CO}_2$  into worthwhile chemicals is the best choice because it is greener and low cost [1].

Therefore, a matter of great concern and any try to reduce  $\text{CO}_2$  emission is importance [2]. There are three reaction types to convert  $\text{CO}_2$  to other valuable products including: Thermal-catalysis, Electro-catalysis and Photo-catalysis [18]. Photo-catalysis was interested because of the increasing non-renewable fossil fuel energy sources. These are coal and natural gas that can be exhausted by the utilizations of light. The reaction is activated by exposure to near UV irradiation under mind ambient condition because the earth has abundant average solar irradiation [19]. In a photocatalytic process when a photocatalyst is exposed to light with sufficient energy, electron and hole are generated in the conduction and valence bands, respectively [20]. Following their migration to the surface of the photocatalyst, redox reactions between the adsorbed species on the surface and the photogenerated charge carriers occur [21]. Therefore, the separation between electron-hole pairs becomes crucial because the recombination of electron and hole has a negative effect on the performance of the photocatalyst.

In this report, photocatalysis reaction is used to solve this problem because economical, affordable and environmentally sustainable source of renewable energy. Titanium dioxide ( $\text{TiO}_2$ ) was selected because it is the most suitable catalyst for this environmental application due to its nontoxicity, biological and chemical inertness [5], resistant oxidization and the stability in preparation for corrosion [19, 22-25]. Consequently, an important activity is the revelation and improvement of photocatalytic activity for feasible applications [26-28]. Recently, the attention of scientist has been attracted by the effect of metal doping [5, 29-32]. The metal doping is Silver (Ag) because it is high stability, great electrical and thermal conductivity appears a favorable doped on  $\text{TiO}_2$  [5].

## 1.2 Objective of Research

Study the effect of silver (Ag) loading and catalyst preparation method on the physicochemical and photocatalytic properties of  $\text{Ag/TiO}_2$  photocatalyst in photocatalytic  $\text{CO}_2$  reduction.

## 1.3 Scope of Research

1.3.1 Prepare pure  $\text{TiO}_2$  and silver (Ag) loading on  $\text{TiO}_2$  catalysts by using Flame spray pyrolysis methods and dry impregnation. The proportion of silver (Ag) loading on  $\text{TiO}_2$  was varied from 1, 3, 5 and 7 wt.%.

1.3.2 The catalyst was characterized by

1.3.3.1  $\text{N}_2$ -physorption (BET)

1.3.3.2 UV-Vis Spectrophotometer

1.3.3.3 X-ray diffractometer (XRD)

1.3.3.4 Photoluminescence spectrometer (PL)

1.3.3.5 Transmission electron microscopy (TEM)

1.3.3.6 X-ray photoelectron spectroscopy (XPS)

1.3.3 The obtain catalyst was tested in the photocatalytic reduction of  $\text{CO}_2$  under UV radiation and the pH of reaction solution was varied adding different concentration of sodium hydroxide (NaOH).

1.3.4 Reaction gases were analyzed by using chromatography (GC-14B and GC-8A, Shimadzu).

#### 1.4 Contribution of Research

This research presents the interested strategy for decreased amount of CO<sub>2</sub> in atmosphere that is the main cause of global warming. Silver (Ag) loading on TiO<sub>2</sub> catalysts were improved the CO<sub>2</sub> photocatalytic reduction activity and selectivity of hydrocarbon (C<sub>x</sub>H<sub>y</sub>).

## CHAPTER II

### LITERATURE REVIEWS

In this research, we interested on the CO<sub>2</sub> photocatalytic reduction of silver (Ag) loading on TiO<sub>2</sub> photocatalyst. The literature reviews discuss about the effect of silver (Ag) loading on physicochemical and photocatalytic properties of Ag/TiO<sub>2</sub> photocatalyst.

#### 2.1 Photocatalytic of CO<sub>2</sub> reduction over TiO<sub>2</sub>

Li et al. [6] studied the synthesis and characterization of Cu<sub>2</sub>O/TiO<sub>2</sub> photocatalysts for H<sub>2</sub> evolution from aqueous solution with different scavengers. They synthesized the Cu<sub>2</sub>O/TiO<sub>2</sub> photocatalysts by an ethanol reduction method using P25 as a support. The photocatalytic reaction was tested under 1 atm at 40°C in 500mL closed quartz reactor system with UV irradiation. There are 3 aqueous solutions (ethylene glycol, methanol, anhydrous ethanol and glycerol) and it was added 450mL/batch. The 2.5mol%Cu<sub>2</sub>O/TiO<sub>2</sub> exhibited the optimal photocatalytic activity which is better than pure P25. The amount of Hydrogen (H<sub>2</sub>) is 2,048.25μmol/g.h in 10vol%methanol solution.

Figure 1: Photocatalytic H<sub>2</sub> evolution rates of the 2.5-Cu<sub>2</sub>O/TiO<sub>2</sub> sample with different scavengers (methanol, anhydrous ethanol, ethylene glycol, glycerol) in reaction solution (10 vol%) under UV-vis light irradiation [6]

Thamaraiselvi et al. [1] studied the photocatalytic reduction of carbon dioxide by using bare and copper oxide impregnated nano Titania catalysts. They found that the nanoparticle  $\text{TiO}_2$  was synthesized by sol-gel method after that the Copper (Cu) was impregnated over  $\text{TiO}_2$  to vary weight percentage (1%, 3%, 5%, 7% and 10% w/w). The bandgap value of CuO impregnated catalyst showed less bandgap values than bare  $\text{TiO}_2$ . The photocatalytic reaction was tested under 1 atm in closed glass reactor system with a 6W mercury lamp and a 150W tungsten lamp as a light source (UV and visible irradiation). The amount of 0.1 g catalyst was suspended into 100mL of 0.2 M sodium hydroxide after that pure  $\text{CO}_2$  gas was purged into the alkali solution until its pH reached 7. The surface area of Degussa P25 is less than the synthesized  $\text{TiO}_2$  by sol-gel method therefore, the synthesized  $\text{TiO}_2$  catalyst exhibited higher activity than Degussa P25. The 3%CuO/ $\text{TiO}_2$  exhibited the optimal photocatalytic activity under UV irradiation because the increased impregnation level of CuO beyond 3%w/w influences to decrease the surface area of  $\text{TiO}_2$  and the reduction ability. The yield of formic acid and formaldehyde is maximum irradiation time at 4 hours. The maximum methanol yield is 4,120 $\mu\text{mol/gcat}$  at 20 hours after that the catalyst was filtered and dried at 60°C for 24 hours. There is methanol yield 3,900 $\mu\text{mol/gcat}$  in second cycle and 3,080 $\mu\text{mol/gcat}$  in third cycles. The methanol yield was decreased due to the loss of catalyst particle during filtration. There are yield of methanol 408 $\mu\text{mol/gcat}$ , formic acid 0.4 $\mu\text{mol/gcat}$  and no formaldehyde under visible irradiation. Both 3%CuO/ $\text{TiO}_2$  was oxidized and reduced catalyst to show the less percentage yield of methanol.

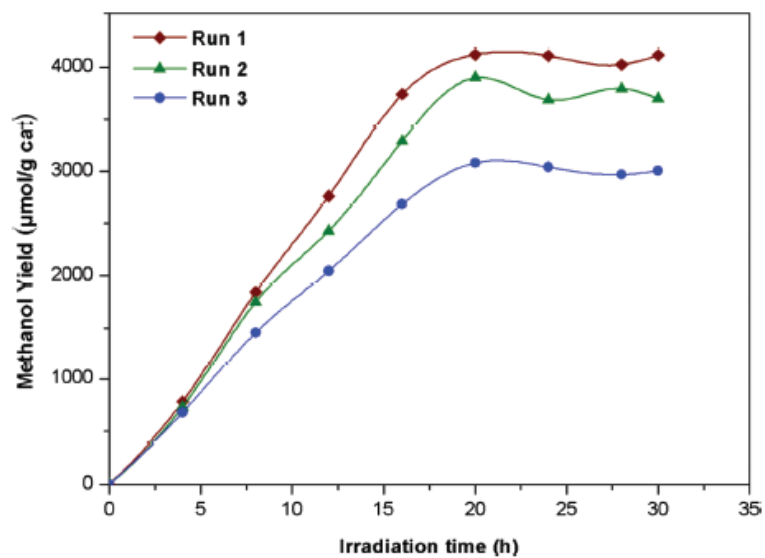

Figure 2: Effect of recycling of 3%CuO/TiO<sub>2</sub> catalyst on the yield of methanol [1]

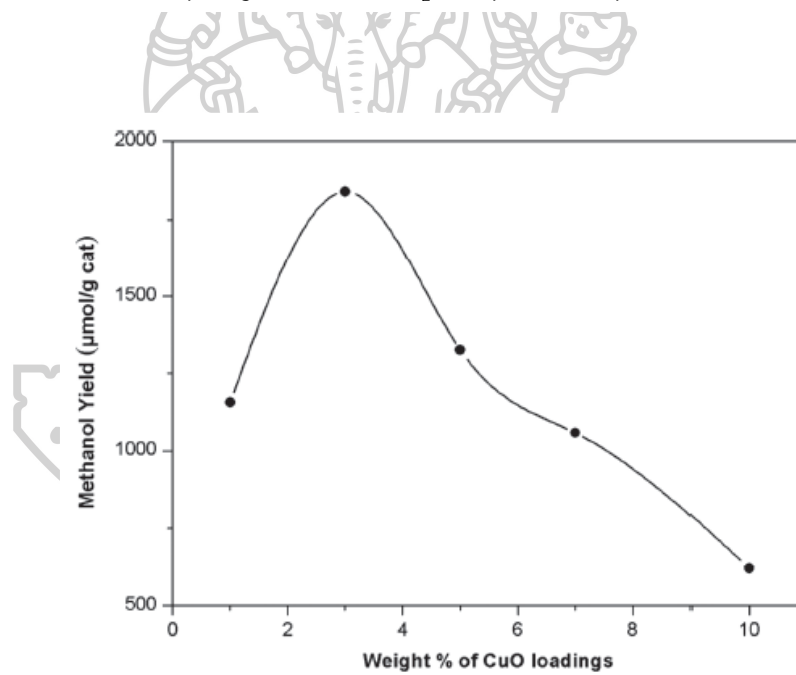

Figure 3: Effect of percentage impregnation of CuO/TiO<sub>2</sub> catalysts on methanol yield [1]

Peng et al. [4] studied the prepared of nitrogen-doped titanium dioxide with visible-light photocatalytic activity using a facile hydrothermal method. They found that The  $\text{TiO}_2$  ( $\text{TiO}_2\text{-HT}$ ) and Nitrogen-doped  $\text{TiO}_2$  ( $\text{N-TiO}_2$ ) nanoparticles were prepared by a direct and simple hydrothermal reaction of a commercial Degussa P25 with tri-ethanol amine (TEA) as a solvent and nitrogen source respectively. The ratio between  $\text{TiO}_2$  and TEA is 0.5 g of commercial P25 powder with 40mL TEA solution after that was mixed in a Teflon-lined stainless autoclave. This was tested at  $140^\circ\text{C}$  for 24 h. Conclusively, the precipitate was centrifuged and that was dried at  $200^\circ\text{C}$  in air for 10 h. The photocatalytic reaction was performed in a 200mL cylindrical glass reactor system with a 1000W Xe lamp as a solar light source about 8% of UV portion. The 20mg of  $\text{N-TiO}_2$  catalyst was suspended into 200mL reaction solution by ultrasonicating for 15 min and the reactant is methyl orange dye (MO). The photocatalytic activity of  $\text{N-TiO}_2$  is higher than P25 but the lowest photocatalytic activity is  $\text{TiO}_2\text{-HT}$  under solar light because  $\text{TiO}_2\text{-HT}$  can't improve without adding a nitrogen source. The photocatalytic activity of  $\text{N-TiO}_2$  is higher than  $\text{N-TiO}_2\text{-NH}_3$  under visible light on the other hand, the P25 and  $\text{TiO}_2\text{-HT}$  were no photocatalytic activity because of wide bandgap energy.

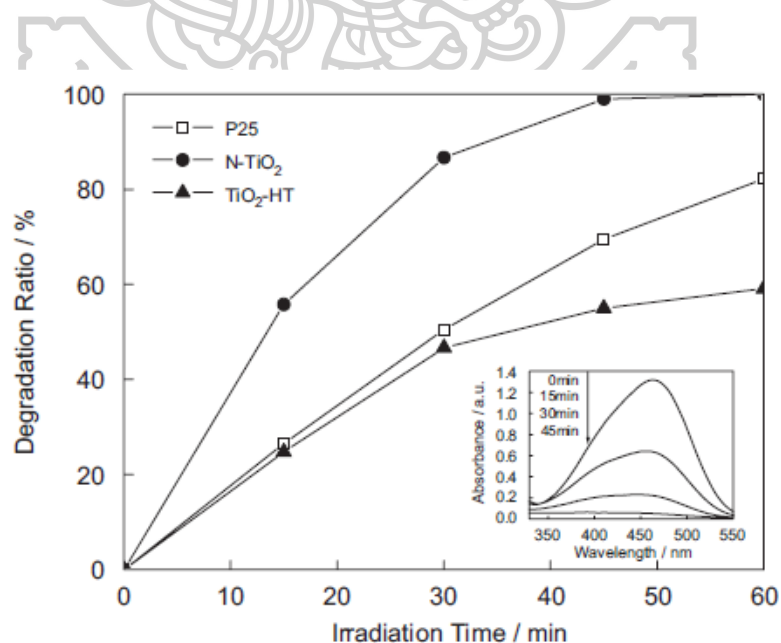

Figure 4: Comparison of the photocatalytic decomposition of methyl orange (MO) under simulated solar light [4]

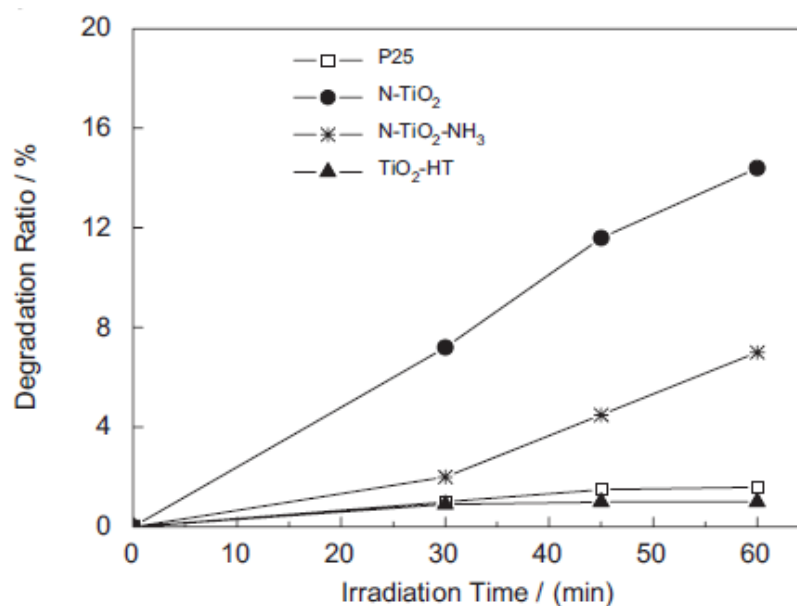

Figure 5: Comparison of the photocatalytic decomposition of methyl orange (MO) under visible light irradiation [4]

Tahir et al. [2] studied gold-indium modified TiO<sub>2</sub> nano catalysts for photocatalytic CO<sub>2</sub> reduction with H<sub>2</sub> as reductant in a monolith photoreactor. They found that the gold-indium modified TiO<sub>2</sub> catalysts were synthesized by sol-gel method. The indium (In) was varied weight percentage (2%, 3.5%, 5%, and 7% w/w) while gold (Au) was used 0.35wt%, 0.5wt% and 0.7wt%. Fixed In-doping 3.5wt% on TiO<sub>2</sub> was doped by varied weight percentage of Au (0.1%, 0.2%, and 0.3% w/w). The main product is carbon monoxide (CO) and other product is methane (CH<sub>4</sub>). The photocatalytic activity of Au-In/TiO<sub>2</sub> is higher than Au/TiO<sub>2</sub> and In/TiO<sub>2</sub>. The monolith that was coated and co-doped monolith catalysts was extracted from the reactor after each cycle.

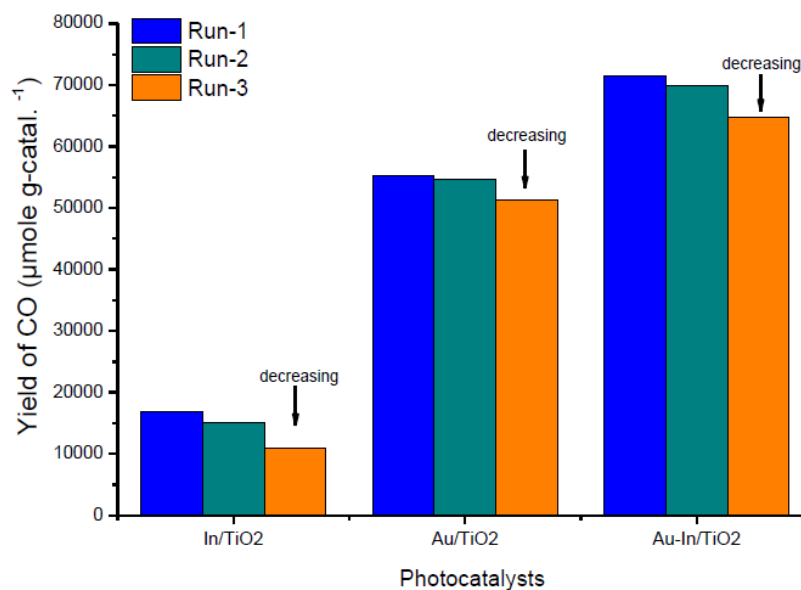

Figure 6: Stability test on photoactivity of 3.5%In/TiO<sub>2</sub>, 0.5%Au/TiO<sub>2</sub> and 0.2%Au-3.5% In-codoped TiO<sub>2</sub> catalyst for CO<sub>2</sub> photoreduction with H<sub>2</sub> to CO at 100°C and CO<sub>2</sub>/H<sub>2</sub> ratio 1.5 [2]

Figure 7: Effects of TiO<sub>2</sub>, In/TiO<sub>2</sub>, Au/TiO<sub>2</sub> and Au-In/TiO<sub>2</sub> monolithic catalysts on conversion (CO<sub>2</sub>, H<sub>4</sub>) and selectivity (CO, CH<sub>4</sub>) [2]

Meng et al. [3] studied the photocatalytic CO<sub>2</sub> conversion over alkali modified TiO<sub>2</sub> without loading noble metal cocatalyst. They found that the amount of CH<sub>4</sub> photocatalytic was fundamentally improved after increasing NaOH. Amount of NaOH was 3 wt.% and the methane (CH<sub>4</sub>) main product was produced 52 mmol/gcat within 6 hours of the reaction. The amount of NaOH (3 wt.%) is a best condition of CO<sub>2</sub> chemisorption. Finally, a reliable reason of CO<sub>2</sub> photoreduction is the surface area of the catalyst.

Figure 8: Evolution amounts of CH<sub>4</sub> and H<sub>2</sub> in the first 6 hours irradiation from photocatalytic CO<sub>2</sub> conversion [3]

## 2.2 Photocatalytic of CO<sub>2</sub> reduction on Ag doped on TiO<sub>2</sub>

Krejčíková et al. [5] studied preparation and characterization of Ag-doped crystalline Titania for photocatalysis applications. They found that the pure TiO<sub>2</sub> and silver-enriched TiO<sub>2</sub> were synthesized by sol-gel method. The concentration of Silver on TiO<sub>2</sub> (Ag/TiO<sub>2</sub>) was varied silver nitrate (AgNO<sub>3</sub>) solution (0.25M, 0.75M, 1.3M and 1.85M) because that was instead of distilled water during catalyst preparation. The photocatalytic reaction was performed under 1 atm in a stirred batch annular reactor system with 8W Hg lamp (254 and 365nm) as a light source. The amount of 0.1 g catalyst was suspended into 100mL of 0.2 M sodium hydroxide (NaOH) after that pure CO<sub>2</sub> gas was purged into the reactor at room temperature and pH7. The surface area of Degussa P25 is less than the Ag doped sol-gel TiO<sub>2</sub> catalysts process therefore they exhibited higher activity than Degussa P25. The Ag doped sol-gel TiO<sub>2</sub> could reduce the bandgap energy and decreased the electron-hole recombination rate. The 5.2wt%Ag/TiO<sub>2</sub> exhibited the optimal photocatalytic activity under the lamp with wavelength at 254nm. There are 2 main products that yield is methanol 2μmol/gcat and methane 10.5μmol/gcat under the lamp of 254nm. The effect of silver doping on TiO<sub>2</sub> catalyst was tested for the photocatalytic reduction of CO<sub>2</sub>. The lamp for this condition is wavelength at 254nm on the other hand, the effect with the lamp of 365nm wavelength was not confirmed.

Figure 9: Sums of methanol and methane yields of all prepared and Degussa catalysts; 254nm lamp – dark, 365nm lamp – light [5]

Kočí et al. [33] studied effect of silver doping on the  $\text{TiO}_2$  for photocatalytic reduction of  $\text{CO}_2$ . They found that the pure  $\text{TiO}_2$  and silver-enriched  $\text{TiO}_2$  were synthesized by sol-gel method. Silver on  $\text{TiO}_2$  ( $\text{Ag}/\text{TiO}_2$ ) was varied silver nitrate ( $\text{AgNO}_3$ ) solution of concentration during catalyst preparation. The photocatalytic reaction was performed in a stirred batch annular reactor system with 8W Hg lamp as a light source. The catalyst of  $1 \text{ g}/\text{dm}^3$  was loaded into 100mL at room temperature under 1 atm. The 7wt% $\text{Ag}/\text{TiO}_2$  exhibited the optimal photocatalytic activity under 254nm lamp. The main product yields that is a methane and methanol are depended on amount of Ag loading on  $\text{TiO}_2$  and other product is formic acid, formaldehyde, ethane, and ethylene. The real Ag content of 7wt% $\text{Ag}/\text{TiO}_2$  was determined by XRF that there is 5.19wt%. There are yield of methanol  $9 \mu\text{mol}/\text{gcat}$  and methane  $8.5 \mu\text{mol}/\text{gcat}$  under the lamp of 254nm. There are two mechanisms for explaining the effect of silver doping on  $\text{TiO}_2$  catalyst: first, the matter of Ag atoms scattering on  $\text{TiO}_2$  crystals (up to 5%) was affected by more effective electron hole pair generation due to shift of absorption edge towards visible light [33] and one more reason, the mechanism from a Schottky barrier at the metal-semiconductor interface around Ag metallic clusters [34]. This causes spatial separation of electron and holes and decreases their recombination rate.

Figure 10: Time dependence of methane yields over the Ag-modified  $\text{TiO}_2$  catalysts [33]

Zhao et al. [35] studied ultrasonic spray pyrolysis synthesis of Ag/TiO<sub>2</sub> nanocomposite photocatalysts for simultaneous H<sub>2</sub> production and CO<sub>2</sub> reduction. They found that the optimal concentration of Ag on TiO<sub>2</sub> is 2 wt.% and it was prepared by ultrasonic spray pyrolysis process. For liquid hydrocarbon fuel production, the final product selectivity of H<sub>2</sub>/CO ratio lowest and negligible CH<sub>4</sub> is in the Fischer-Tropsch process. The electrons and protons in the photocatalytic reaction were competed for H<sub>2</sub> production and CO<sub>2</sub> reduction processes. The ultrasonic spray pyrolysis method is convention for wet impregnation process with the advantages of smaller Ag nanoparticles because the ultrasonic spray pyrolysis method leads to Ag dispersion on TiO<sub>2</sub> and a higher fraction of metallic Ag species better than wet impregnation method. This cause resulted in good photocatalytic activity.

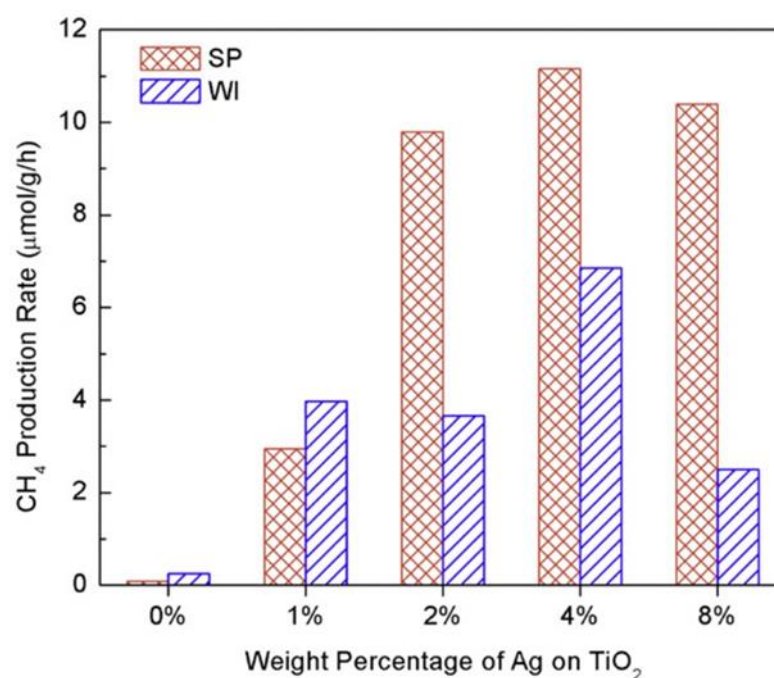

Figure 11: Rates of photocatalytic CO<sub>2</sub> reduction to CH<sub>4</sub> (b) for Ag/TiO<sub>2</sub> eSP and Ag/TiO<sub>2</sub> eWI samples at different Ag concentration [35]

Yu et al. [36] studied photocatalytic reduction of  $\text{CO}_2$  over  $\text{Ag}/\text{TiO}_2$  nanocomposites prepared with a simple and rapid silver mirror method. They found that the Ag doped on  $\text{TiO}_2$  nanocomposite was prepared by a simple and rapid silver mirror reaction. The 1.5wt% $\text{Ag}/\text{TiO}_2$  showed the optimal photocatalytic reaction. The effect of increasing Ag loading on  $\text{TiO}_2$  from 1.0wt% to 1.5wt% leads to an accumulation of electron. However, the Ag loading on  $\text{TiO}_2$  was increased to 2.0wt% which the generation rate was decreased to 1.17mol/g.h  $\text{CH}_4$ . The effect may be happened from the quality factor of the plasmon resonance because the Ag is directly related to the photocatalytic activity.

Figure 12:  $\text{CH}_4$  evolved during the photocatalysis using pure  $\text{TiO}_2$  and 1, 1.5, 2.0 wt%  $\text{Ag}/\text{TiO}_2$  under UV-visible irradiation in gas phase photoreaction [36]

### 2.3 Preparation by Flame spray pyrolysis

Flame spray pyrolysis (FSP) is generally known as a method for making nanoparticles such as fume silica, Titania, and carbon black in large quantity at low cost [37]. It is a relatively new process for one-step synthesis of supported metal catalysts. The nanoparticles were generated by the FSP have shown high purity, controlled stoichiometry and metal crystalline because the flame could be maintained at high temperatures [38]. FSP was appeared an attractive fast and single step catalyst preparation method [39].

Gunawan et al. [40] studied reversible antimicrobial photoswitching in nanosilver. They found that the 5 at% Ag/TiO<sub>2</sub> nanoparticles were prepared by the FSP of titanium tetraisopropoxide and silver benzoate co-dissolved in acetonitrile/xylene mixture. The dispersed silver nanoparticle on semiconductor support (TiO<sub>2</sub>) was synthesized in a one-step of flame spray pyrolysis (FSP) of silver benzoate and titanium isopropoxide co-dissolved in acetonitrile/xylene. This research used this technique because the FSP is a proven scalable and large production for the synthesis of high-quality nanoparticles or fine particles.

Teoh et al. [41] studied a perspective on the flame spray synthesis of photocatalyst nanoparticles. He found that Flame spray pyrolysis (FSP) include Pt/TiO<sub>2</sub>, Ag/TiO<sub>2</sub>, Au/TiO<sub>2</sub> and Ag/ZnO. The noble metal has relatively low boiling and sublimation point of the metal compared to oxide photocatalyst that is the first segregation of the noble metals as nanosized deposits during FSP. After that, the former precipitates at a later stage in the flame after the precipitation of the oxide photocatalyst support was low solubility of the two phases which in a different way improved bulk doping rather than surface deposition.

Mekasuwandumrong et al. [37] studied influence of flame conditions on the dispersion of Pd on the flame spray-derived Pd/TiO<sub>2</sub> nanoparticles. They found that the one-step flame spray pyrolysis (FSP) is a method for synthesized 5wt%Pd/TiO<sub>2</sub> under different flame conditions. These catalysts were characterized by X-ray diffraction (XRD) and transmission electron microscopy (TEM). The results of Pd/TiO<sub>2</sub> about an average particle sizes of were increased from 9.7 to 24.6 nm when increasing the precursor concentration and feed flow rate as well as reduction of the

O<sub>2</sub> dispersing gas during FSP synthesis. The amounts of CO chemisorption were higher on the larger size FSP-made Pd/TiO<sub>2</sub> nanoparticles showed %Pd dispersion that Pd/TiO<sub>2</sub> particle size was increasing on the other hand the BET surface area and %anatase phase content was decreased. The shorter residence time in flame and the lower combustion energy (enthalpy density) caused Pd covered on surface more than before. It is suggested that the formation of Ti–O groups.

## CHAPTER III

### THEORY

This chapter provided some background information necessary for this study such as the synthesis of catalyst by dry impregnation and flame spray pyrolysis (FSP), The CO<sub>2</sub> photocatalytic reduction and the photocatalyst. The details were detailed as follow.

#### 3.1 Dry impregnation

Dry impregnation or incipient wetness impregnation is a principal technique for preparation or synthesis of a heterogeneous catalyst. Dry impregnation shows schematically in Figure 13. Normally, the metal precursor was dissolved in a solution or deionized water after that it is dropped to a support catalyst. The feature of a support catalyst likes a powder. The pore of support catalyst was filled by metal containing solution. The volume of this solution equals a pore volume of a support catalyst. The capillary action is a metal solution to be adsorbed into a pore of catalyst. The metal solution is adsorbed until the pore volume is saturated or exceeded. The texture of catalyst is similar to mud or sticky and the capillary action is slower than initial. After that the catalyst is dried and calcined to eliminate the volatile components within the solution. So, the metal is deposited on a surface of support catalyst. The concentration of metal coated on support catalyst is depended on mass transfer condition of pore catalyst [42].

Figure 13: The procedure of dry impregnation

### 3.2 Flame spray pyrolysis

Flame spray pyrolysis (FSP) is synthesis method of catalyst that can prepare nanostructure powder with high specific surface area in one step process and high catalytic performance [42]. No post-production treatment step requires, and the nanoparticles are ready to use. The nanoparticle is prepared by this method such as fume silica, titania and carbon black in large quantity at low cost [41].

Flame spray pyrolysis (FSP) shows schematically in figure 14 which uses for the synthesis of metal oxide and doped metal oxide particles. The combustion of the precursor solution is sprayed droplets which is used as the basis for the preparation of a compound oxide nano powder. In the middle of the device was fed the precursor solution through a capillary. An annular aperture around the capillary tube is used for liquid feed through a middle of capillary that this liquid feed is atomized under high pressure dispersion gas. The organometallic precursors decomposition and the organic compounds undergo complete combustion was made by methane mixed with oxygen flame let ignites the aerosolized precursor solution under high temperature flame. The primary particles form of pure metals or oxides was nucleated and condensate by the metallic or semi-metallic components of the precursor. The high temperature region of the flame was taking place some aggregation on the other hand quenching owing to productive radiation and convection quickly stops the sintering [43]. Accordingly, the primary particles are going to remain small particle though they do form loose agglomerates in the gas stream owing to high particle concentration and during powder collection [43]. Flame spray pyrolysis (FSP) can produce nanoparticle metal in 1-200 nm by using a substrate that is unexpansive and affordable. It was controlled the production rate of up to 250 grams/hour. The amount and rate of production is depended on conditions. The particle formation and configuration were prepared by FSP. The mechanism in the synthesis transits from a state to gas or vapor particle (gas to particle conversion) or aqueous aerosol droplets into particles (droplet to particle conversion). These are a fundamental process in this synthesis technique. In this section, we further review these particles from in sequential stages of spray

formation, droplet evaporation, nucleation and condensation, coagulation and growth by coalescence and particles aggregation.

After synthesis, obtained particles are retained on the filter paper with special heat resistant properties. The spray of aerosols from the initial solution occurs the formation of the flame of a gas that helps to ignite the methane and oxygen. This will cause the evaporation and combustion of aerosols. Also, using oxygen distributes of the aerosols spray ( $O_2$  dispersion) and controls the oxidation state ( $O_2$  sheet gas) to perfect. Fuel supports the methane gas in system. There is a separate flow control that is clearly out of the box solution to the initial spray. All the gas flow rates were controlled by mass flow controller in the aerosol was changed status quickly. Therefore, the substrate solution into the system will allow the direct reaction with gaseous oxidant oxygen species.

Figure 14: The procedure of Flame spray pyrolysis (FSP)

### 3.3 CO<sub>2</sub> photocatalytic reduction of TiO<sub>2</sub> and Ag/TiO<sub>2</sub> photocatalyst

The photocatalysis process has been widely investigated. To choose titanium dioxide (TiO<sub>2</sub>) as a photocatalyst is nontoxic, abundant, high stability and low cost [44, 45]. Table 3.1 lists some physical properties of rutile, anatase and brookite [39, 46, 47]. Titanium rutile phase and anatase phase exhibited physical properties that slight differences exist. A band gap of both Titanium phases is 3.0–2.3 eV that is affect about reflect visible light while Titanium anatase phase was reflected covering long-wave ultraviolet (UVA) light and visible light as a wider electromagnetic wave. The physical property of Titanium rutile phase absorbs violet visible light on the other hand anatase phase absorbs UVA region to show photo-reduced catalytic effects. Figure 15 shows crystallographic structures of rutile and anatase.

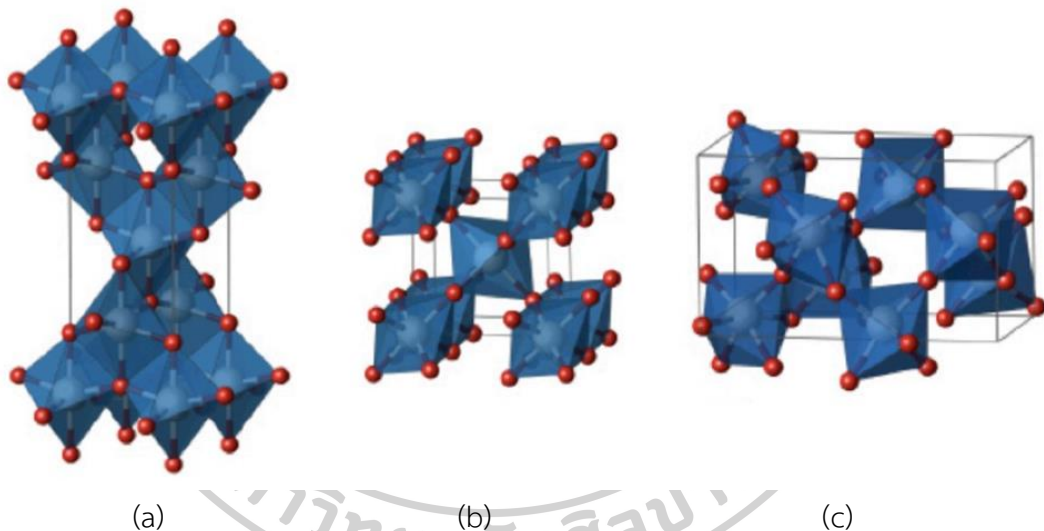

Figure 15: Crystallographic structure of (a) Anatase, (b) Rutile and (c) Brookite

Table 1: Physical properties of titanium dioxide [48]

Material	Anatase	Rutile	Brookite
Composition	TiO <sub>2</sub>	TiO <sub>2</sub>	TiO <sub>2</sub>
Chemical formula weight	79.87	79.87	79.87
Crystal structure	Tetragonal	Tetragonal	Orthorhombic
Temperature (°C)	25	25	25
a (Å)	3.7842	4.5845	9.184
b (Å)	3.7842	4.5845	5.447
c (Å)	9.5146	2.9533	5.145
$\alpha$ (deg)	90	90	90
$\beta$ (deg)	90	90	90
$\gamma$ (deg)	90	90	90
Unit cell volume (Å) <sup>3</sup>	136.25	62.07	257.38
Density (g/cm <sup>3</sup> )	3.895	4.2743	4.123
Molar volume	20.156	18.693	19.377

The electron of the valance band of TiO<sub>2</sub> is excited by energy and the photocatalysis mechanism diagram of TiO<sub>2</sub> shows on figure 16. The ultraviolet radiation was generated from sunlight or illuminated light source (fluorescent lamps) as an energy. This energy produces the pairs of electrons and holes. The electron is excited by energy when this energy has more than band gap energy. The excess energy of this excited electron led to the conduction band [49] from valance band of TiO<sub>2</sub> because that is produced a negative-electron and positive-hole (Eq. (1)). This stage is appeared with semiconductor photocatalyst. The main issue in the use of TiO<sub>2</sub> is related to low efficiency. The efficiency is limited for activated wavelength because the wide band gap is ~3.2eV that there is only 3-5% of the total solar radiation [50, 51]. The efficiency of semiconductor catalyst is modified by in two ways: doping transition-metal, non-metal or combination. Non-metal is Nitrogen-doped [52, 53], Carbon-doped [54, 55], Fluorine-doped [55, 56], Sulfur-doped [55, 57], Nitrogen-Carbon co-doped TiO<sub>2</sub> [55, 58], transition-metal is Platinum [59, 60], Silver

[27, 30, 33, 36, 61, 62], Copper [63] and Vanadium [64] or combination is Nitrogen-Platinum co-doped TiO<sub>2</sub> [55, 65] and Fluorine-Iron co-doped TiO<sub>2</sub> [45, 55]. The UV illumination for the energy source excited the electron that is excited from valance band to conduction band. This step led to raise electron hole. The water or other molecule that there are a lot of electron or give an electron to is an electron donor (Eq. (2) - (3)). The electron is attached by an electron donor that the function of an electron donor prevents an electron to turn back to hole. In an aqueous solution, the photocatalysis process generated to transfer the electron and instantly reacted with oxygen to form superoxide radicals (O<sub>2</sub><sup>•-</sup>). The positively charged hole built the hydroxyl groups to form hydroxyl radicals (HO<sub>2</sub><sup>•</sup>) or hydrogenperoxide (H<sub>2</sub>O<sub>2</sub>). The superoxide free radicals and hydroxyl radicals are built at the same time (Eq. (4)-(9)). The properties of these are a high oxidizing ability because of sensitivity. These free radicals degraded solvent into the small molecules [67]. The photocatalysis process consists of the process of transferring the charge of the carrier to organic matter while absorbing the organic matter on the semi-conducting substance. This is considered to reduce the combination of electrons and holes that causes loss of work efficiency during the merging of electrons and holes. It will heat out (Eq. (10)).

The Ag-coated TiO<sub>2</sub> was synthesized by dry impregnation or FSP which demonstrated outstanding efficiency in photocatalytic degradation. Figure 17 shows the excitation–enhancement synergistic mechanism for photocatalytic reduction of CO<sub>2</sub> on Ag/TiO<sub>2</sub> composite [16]. The high photocatalytic activity in TiO<sub>2</sub> can be ascribed to Ag because that decreases the recombination rate of electron-hole pairs.

Eq. (11) – (15) showed the process of photocatalytic reduction  $\text{CO}_2$ . The photoreaction of the  $\text{Ag}/\text{TiO}_2$  composite is participated about the electrons and holes on the surface photocatalyst [16]. The  $\text{H}_2\text{O}$  or  $\text{OH}^-$  to form hydroxyl radicals ( $\cdot\text{OH}$ ) are oxidized by activated  $h^+$  (VB) and  $\text{O}_2$  and  $\text{H}^+$  like a function of  $\text{H}_2\text{O}$  or  $\text{OH}^-$  [66].  $\text{CO}_2$  reduction and produced methanol or other hydrocarbons was generated by  $\text{H}^+$  and high active  $e^-_{\text{SP}}$  [67, 68]. The six  $e^-_{\text{SPR}}$  are required to convert the  $\text{C}^{4+}$  of  $\text{CO}_2$  into  $\text{C}^{2-}$  of  $\text{CH}_3\text{OH}$  was indicated by Equation (15).  $\text{Ag}$  nanoparticles play a crucial role in the above process for electron trapping was appeared by it in the same way surface plasmon resonance (SPR) enhancement [69].

Figure 16: The photocatalysis mechanism diagram of  $\text{TiO}_2$  [70]

Figure 17: The excitation–enhancement synergistic mechanism for photocatalytic reduction of  $\text{CO}_2$  on  $\text{Ag}/\text{TiO}_2$  composite [36]

## CHAPTER IV

### METHODOLOGY

This chapter describes the experimental procedures for synthesis of TiO<sub>2</sub> and Ag/TiO<sub>2</sub> for CO<sub>2</sub> photocatalytic reduction reaction. This chapter consists three parts. The first part explains the materials and the preparation method of nanoparticles by dry impregnation and flame spray pyrolysis. Second part shows the details of characterization techniques. Finally, show the reaction evaluation for CO<sub>2</sub> photocatalytic reduction.

#### 4.1 Materials

The chemicals were used in this research that shows in Table 2 as a precursor for catalyst preparation (Flame spray pyrolysis and Impregnation method).

**Table 2: The details of chemical were used in the catalyst preparation.**

Chemical	Formula	Grade	Suppliers
Titanium (IV) isopropoxide	Ti{(OCH(CH <sub>3</sub> )) <sub>2</sub> } <sub>4</sub>	97%	Sigma-Aldrich
Titanium (II) oxide	TiO <sub>2</sub>	P25 grade	Chula University
Butanol	C <sub>4</sub> H <sub>9</sub> OH	99.4%	Labscan
Methanol	CH <sub>3</sub> OH	99.4%	Sigma-Aldrich
Silver (I) nitrate	Ag(NO <sub>3</sub> )	99.5%	Merck
Sodium hydroxide	NaOH	97%	KEMAUS

#### 4.2 Catalyst preparation

##### 4.2.1 Preparation of Ag/TiO<sub>2</sub> catalyst by Dry impregnation

It was prepared by dry impregnation. First, the silver was dissolved and dropped into TiO<sub>2</sub> support catalyst until it saturates because of calculate the total pore volume from this step. Second, the thick slurry was dried at 110°C overnight after that the powders were calcined at 400°C 4 hours. The content of Ag was varied 1wt%Ag, 3wt%Ag, 5wt%Ag and 7wt%Ag. The procedure of dry impregnation shows in Figure 13.

#### 4.2.2 Preparation of TiO<sub>2</sub> and Ag/TiO<sub>2</sub> catalyst by Flame sprays pyrolysis method

##### TiO<sub>2</sub> non-loading

Titanium (IV) butoxide was dissolved in xylene. The content of bare Titanium (IV) butoxide obtains the final FSP nanoparticles precursor solution.

##### Ag loading on TiO<sub>2</sub>

Silver (I) nitrate and Titanium (IV) butoxide were dissolved in xylene. The content of Pt loading was varied from 1wt%Ag, 3wt%Ag, 5wt%Ag and 7wt%Ag to obtain the final FSP nanoparticles precursor solution. The preparation condition of non-loading and Ag loading on TiO<sub>2</sub> prepared by FSP method was described below. The precursor solution was fed into a flame spray pyrolysis apparatus by a syringe pump. The rate of syringe pump is 5 mL/min of precursor solution that was dispersed into fine droplets by a gas-assist nozzle and fed 5 L/min of oxygen. The orifice gap area at the nozzle was adjusted 1.5 bars because of maintained the pressure drop at the capillary tip. A ring around the nozzle outlet is the position for ignition. The ignited spray was fed 3 L/min oxygen and 1.5 L/min methane for supporting flame. An additional 10 L/min of oxygen as sheath for the supporting flame was provided by a sintered metal plate ring (8 mm wide, starting at a radius of 8 mm) [41]. A glass fiber filter with a vacuum pump used for collected the product particles. The procedure of FSP shows in Figure 14.

### 4.3 Catalyst characterization

#### 4.3.1 N<sub>2</sub>-physiosorption (BET)

N<sub>2</sub>-physiosorption was determined textural properties as an average pore size and a pore volume. The 0.1 g of catalyst was pretreated at 180°C for 3 hr. under high vacuum. The Dewar flask was contained liquid nitrogen that the sample port was dipped in it. The volume of N<sub>2</sub> was measured at -196 °C using as the different N<sub>2</sub> partial pressure. Brunauer-Emmett and Teller (BET) used to find specific surface area. Pore volume and pore diameter were calculated by Barret – Joyner – Halenda (BJH).

Figure 18: N<sub>2</sub>-physicisorption (Belsorpmini 2)

#### 4.3.2 UV-Visible adsorption spectrometer (UV-Vis)

UV-Vis Spectrophotometer was used to find maximum wavelength and band gap energy ( $E_g$ ) of photocatalyst. This was absorbed by sample in rang of UVA, UVB, UVC or visible light. LAMDA 650 UV/Vis spectrophotometer was used for measured the UV-vis absorption spectra and band gap energy of sample powders. This spectrophotometer was scanned around wavelength of 200–900 nm and used a UV Win Lab software from Perkin-Elmer.

Figure 19: UV-Vis spectrometer (T92+ UV-Vis spectrometer PG Instruments Limited)

#### 4.3.3 X-ray diffractometer (XRD)

X-ray diffractometer (XRD) was identified the crystal structures, composition and state of crystalline particle by electromagnetic radiation. X-ray diffractometer can identify a crystalline material and provide informative crystal structure. This experiment used diffractometer with  $\text{CuK}\alpha$  radiation when it performs operation at 40 kV and 30 mA.

Figure 20: X-ray diffraction (Model D8 Advance: Bruker AXS, Germany with  $\text{CuK}\alpha$  radiation)

#### 4.3.4 Photoluminescence Spectrometer (PL)

The recombination rate analysis by Photoluminescence Spectrometer for excite on wavelength 340 - 550 nm at Faculty of Engineering, Chulalongkorn University.

Figure 21: Photoluminescence Spectrometer (Fluoramax<sup>®</sup> by Horiba and using Xenon lamp source)

#### 4.3.5 Transmission electron microscopy (TEM)

The morphology and catalyst particle size were determined by Transmission electron microscopy (TEM) with bright-field and dark-field and using Olympus TECNAI 20 TWIN Transmission electron microscopy at 120 kV. The samples were dispersed in ethanol as a solution and liquid solution was dropped into a mesh of carbon grid. This was coated by holey carbon and dried on a filter paper before scanning. The scanning was done many times in difference area because of fine dispersion.

Figure 22: Transmission electron microscopy (Olympus TECNAI 20 TWIN)

#### 4.3.6 X-ray photoelectron spectroscopy (XPS)

The binding energy and surface composition of catalysts was determined by X-ray photoelectron spectroscopy (XPS) with  $MgK\alpha$  X-ray source as a primary excitation as the AMICUS photoelectron spectrometer. XPS equipment was get with a 0.1 eV energy step at a pass energy of 75 eV. The controlled software was KRATOS VISION2.

Figure 23: X-ray photoelectron spectroscopy (AMICUS photoelectron spectrometer)

#### 4.4 Reaction test

The photocatalytic reaction was carried out in a gas circulation system and was performed under the set of UV 6 lamps (UV irradiation). The volume of Quartz reactor is 400 cm<sup>3</sup>. Photocatalyst for this experiment used 0.3 g with 100ml DI water. The CO<sub>2</sub> gas was purged by a bubble for 30 min with flow rate 100 ml/min after that turned on the lamps and stirred 3 hours under room temperature. The gas production was analyzed by gas chromatograph with a thermal conductivity detector (GC-TCD) and liquid production was analyzed by gas chromatograph with a flame ionization detector (GC-FID).

Figure 24: The procedure of Reaction test

## CHAPTER V

### RESULT AND DISCUSSION

The objective of this research focused on the study of effect silver (Ag) metal doped on titanium dioxide. This result showed the physicochemical and photocatalytic properties of pure TiO<sub>2</sub> and Ag/TiO<sub>2</sub> photocatalysts in photocatalytic CO<sub>2</sub> reduction. Therefore, the result and discussion were explained in this chapter that there are two section: physicochemical properties characterization and photocatalytic activity.

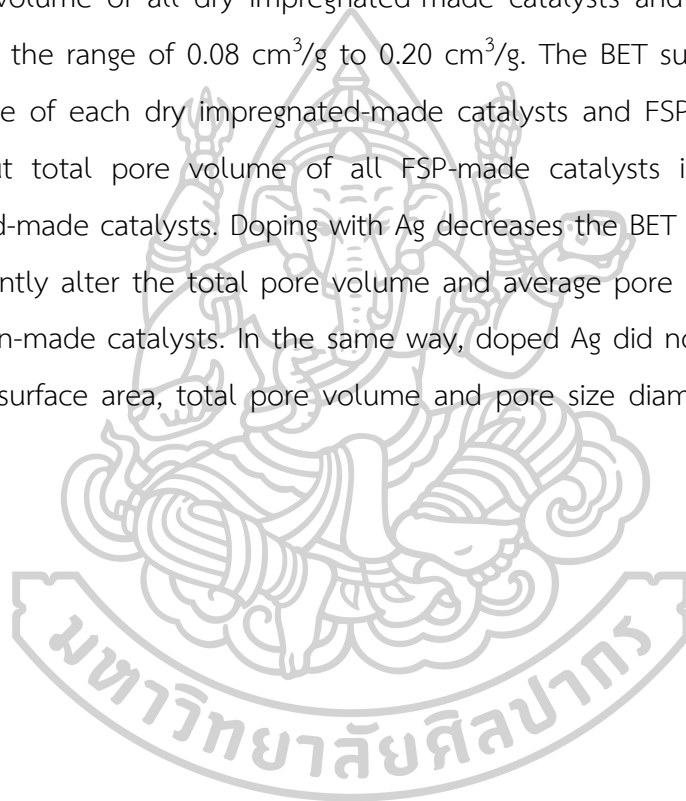

**Table 3: The specimen designation of the catalysts in this work**

Sign	Detail of sign
P25-TiO <sub>2</sub>	The TiO <sub>2</sub> commercial catalyst P25 (Degussa)
IM-1wt% Ag/TiO <sub>2</sub>	Impregnated Ag doped on P25 catalyst at 1wt%
IM-3wt% Ag/TiO <sub>2</sub>	Impregnated Ag doped on P25 catalyst at 3wt%

## 5.1 Physicochemical properties characterization

### 5.1.1 N<sub>2</sub>-physicorption (BET)

N<sub>2</sub>-physicorption is used to determine the BET surface area, total pore volume and average pore size diameter of all photocatalysts. These results are summarized in the Table 4 and the adsorption/desorption isotherm of all catalysts are exhibited in figure 25-26. The BET surface area of all dry impregnated-made catalysts and FSP-made catalysts exhibited in the range of 40 m<sup>2</sup>/g to 56 m<sup>2</sup>/g. The total pore volume of all dry impregnated-made catalysts and FSP-made catalysts exhibited in the range of 0.08 cm<sup>3</sup>/g to 0.20 cm<sup>3</sup>/g. The BET surface area and total pore volume of each dry impregnated-made catalysts and FSP-made catalysts are similarly but total pore volume of all FSP-made catalysts is less than all dry impregnated-made catalysts. Doping with Ag decreases the BET surface area but did not significantly alter the total pore volume and average pore size diameter of dry impregnation-made catalysts. In the same way, doped Ag did not significantly affect in the BET surface area, total pore volume and pore size diameter of flame-made catalysts.

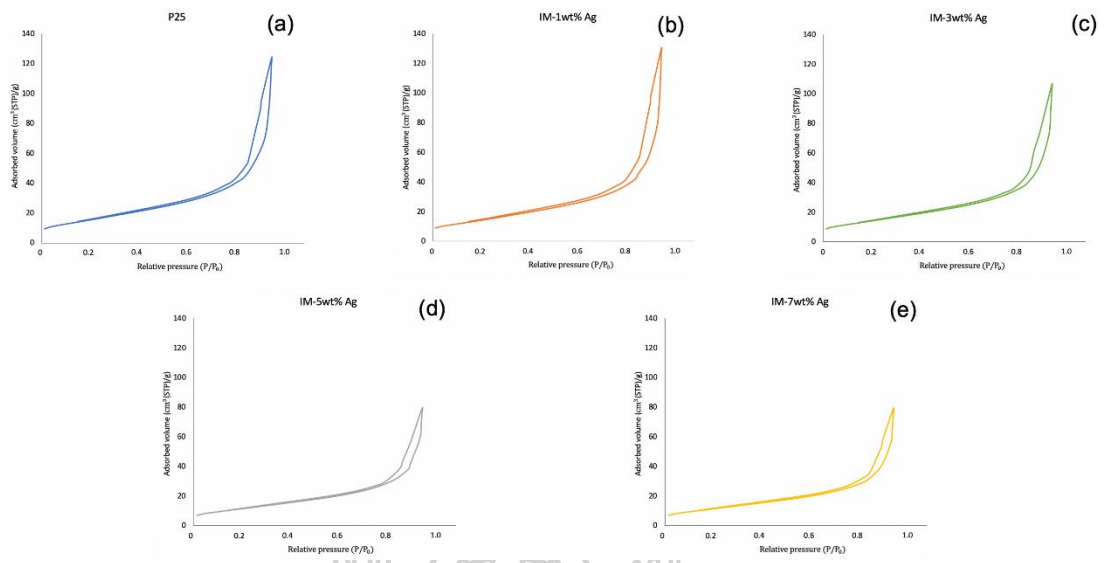

Figure 25: The  $N_2$ -adsorption/desorption isotherm of a) P25, b) IM-3wt% Ag/TiO<sub>2</sub>, c) IM-3wt% Ag/TiO<sub>2</sub>, d) IM-5wt% Ag/TiO<sub>2</sub> and e) IM-7wt% Ag/TiO<sub>2</sub>

FSP-7wt% Ag/TiO <sub>2</sub>	51.22	0.09	7.13	

### 5.1.2 UV-Vis spectrophotometer

The UV-Vis absorption spectra of all the dry impregnation (IM) and the flame spray pyrolysis (FSP) catalysts were compared with P25-TiO<sub>2</sub> in figure 27-28. Figure 27 shows the UV-Vis absorption spectra of all the photocatalysts prepared by dry impregnation (IM) together with P25 support. There are five photocatalysts including 1wt% Ag/TiO<sub>2</sub>, 3wt% Ag/TiO<sub>2</sub>, 5wt% Ag/TiO<sub>2</sub>, 7wt% Ag/TiO<sub>2</sub> and commercial TiO<sub>2</sub> (P25). UV-Vis bands of photocatalysts showed the sharp absorption band at wavelengths less than 400 nm. The adsorption at the wavelength higher than 400 nm increased after doping amounts of Ag increased. The band structure of commercial TiO<sub>2</sub> was associated with Impregnated Ag doped on P25 catalysts. Figure 28 shows the UV-Vis absorption spectra of the photocatalysts prepared by flame spray pyrolysis (FSP). There are five photocatalysts samples including 1wt% Ag/TiO<sub>2</sub>, 3wt% Ag/TiO<sub>2</sub>, 5wt% Ag/TiO<sub>2</sub>, 7wt% Ag/TiO<sub>2</sub> and pure TiO<sub>2</sub>. Similarly, the flame spray pyrolysis catalysts showed the sharp absorption band at wavelengths less than 400 nm. The Increasing of Silver (Ag) doped on FSP-TiO<sub>2</sub> caused the increased of absorbance at the wavelength higher than 400 nm. The band gap energy (E<sub>g</sub>) of IM-photocatalyst and FSP-photocatalyst were showed in Table 5 calculated from figure 29-30. The result of this table was extrapolated from Tauc plots of  $(h\nu_{\alpha})^{1/2}$  as a function of photon energy (hν). The band gap energy (E<sub>g</sub>) was decreased owing to increasing of Silver (Ag) doped on TiO<sub>2</sub>. The photosensitivity of all photocatalysts and the absorption edge in visible light region (400-700 nm) are improved by decreasing of E<sub>g</sub> and Fermi level was reduced due to decreasing of E<sub>g</sub>.

Figure 27: The UV-Vis absorption spectra of IM-Ag/TiO<sub>2</sub> and P25-TiO<sub>2</sub> photocatalysts

### 5.1.3 X-ray diffractometer (XRD)

The XRD pattern of TiO<sub>2</sub> and Ag/TiO<sub>2</sub> photocatalysts were shown in fig 31-32. The diffraction peaks of anatase TiO<sub>2</sub> can be observed at  $2\theta = 25.3^\circ, 36.9^\circ, 37.9^\circ, 38.5^\circ, 48.0^\circ, 54.9^\circ, 55.0^\circ, 62.1^\circ, 68.9^\circ, 70.3^\circ, 75.1^\circ$  and  $76.0^\circ$  and the small diffraction peaks of rutile phases was also found at  $2\theta = 27.36^\circ$  (110) [71]. All samples, exhibited the peaks mainly of only anatase and rutile TiO<sub>2</sub> phase as a main peak [72]. The characteristic peaks positions of all Ag metal/oxide phases were not observed because of the very high dispersion of Ag phase on both catalysts. However, the FSP-7wt% Ag/TiO<sub>2</sub> exhibited the small two peaks at  $2\theta = 38.2^\circ$  (111) and  $77.6^\circ$  (311) which are the crystallographic planes of face-centered cubic (fcc) silver crystals [73, 74]. The ratio of pure anatase and rutile phase have been calculated using Debye-Scherrer's equation (see Appendix B) and the results are summarized in table 6.

Figure 31: XRD patterns of P25 and IM-Ag/TiO<sub>2</sub>Figure 32: XRD patterns of FSP-TiO<sub>2</sub> and FSP-Ag/TiO<sub>2</sub>

Table 6: The crystalize phase and crystalize size

Photocatalysts	Crystalize phase	Crystalize size (nm)	%Compositions
P25-TiO <sub>2</sub>	Anatase <sup>1</sup> , Rutile <sup>2</sup>	28.49 <sup>1</sup> , 29.47 <sup>2</sup>	80.79 <sup>1</sup> , 19.21 <sup>2</sup>

#### 5.1.4 Photoluminescence spectrometer (PL)

The PL spectra of the P25-TiO<sub>2</sub>, impregnation-made and the flame-made were shown in figure 33-34. The PL emission spectra indicates the electron-hole recombination rate by detecting the release energy from the electron-hole recombination process. The PL emission spectra exhibited many peaks within visible region at around 430nm, 450nm and 470 nm, which were excited under 250 nm. The self-trapped electron on TiO<sub>2</sub> region communicated with the peak around 436nm [75]. The oxygen vacancies with two trapped electrons on TiO<sub>2</sub> surface were indicated at 469, 484 and 492nm [76, 77]. The PL spectra was decreased when Ag doping content increased, whereas the PL spectra of P25 was similar to 1wt%Ag/TiO<sub>2</sub>. Increased Ag led to disappeared new emission peak [33]. Figure 34 exhibits the PL emission spectra of Ag/TiO<sub>2</sub> photocatalysts prepared by flame spray pyrolysis (FSP). The PL spectra was decreased by increased of Ag loading. The results suggest that the Ag<sup>+</sup> on conduction band of TiO<sub>2</sub> leads to decrease the electron-hole recombination rate.

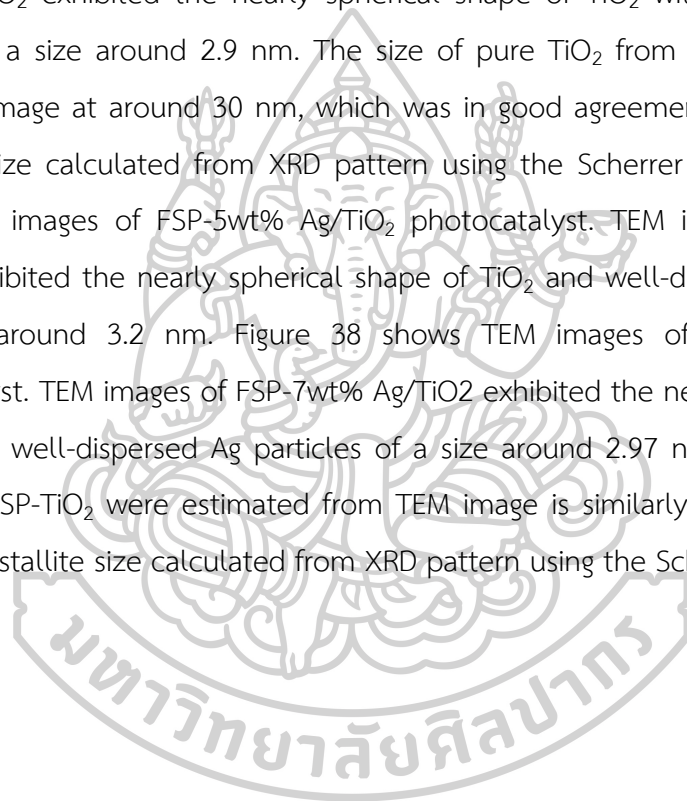

Figure 34: PL spectra of pure TiO<sub>2</sub> and FSP-TiO<sub>2</sub> photocatalysts

### 5.1.5 Transmission electron microscopy (TEM)

Transmission electron microscopy (TEM) are used to determine the size and morphology of as prepared photocatalysts. TEM images and the size distribution of particles graph of all Ag/TiO<sub>2</sub> photocatalysts are presented in figure 35-38 and figure 39 respectively. TEM images of IM-5wt% Ag/TiO<sub>2</sub> exhibited the nearly spherical shape of TiO<sub>2</sub> and well-dispersed Ag particles with an average particle size around 3.2 nm. Figure 36 shows TEM images of IM-7wt% Ag/TiO<sub>2</sub> photocatalyst. TEM images of IM-7wt% Ag/TiO<sub>2</sub> exhibited the nearly spherical shape of TiO<sub>2</sub> with well-dispersed Ag particles of a size around 2.9 nm. The size of pure TiO<sub>2</sub> from P25 were estimated from TEM image at around 30 nm, which was in good agreement with the value of crystallite size calculated from XRD pattern using the Scherrer equation. Figure 37 shows TEM images of FSP-5wt% Ag/TiO<sub>2</sub> photocatalyst. TEM images of FSP-5wt% Ag/TiO<sub>2</sub> exhibited the nearly spherical shape of TiO<sub>2</sub> and well-dispersed Ag particles of a size around 3.2 nm. Figure 38 shows TEM images of FSP-7wt% Ag/TiO<sub>2</sub> photocatalyst. TEM images of FSP-7wt% Ag/TiO<sub>2</sub> exhibited the nearly spherical shape of TiO<sub>2</sub> and well-dispersed Ag particles of a size around 2.97 nm. The size of pure TiO<sub>2</sub> from FSP-TiO<sub>2</sub> were estimated from TEM image is similarly which confirms the value of crystallite size calculated from XRD pattern using the Scherrer equation.

### 5.1.6 X-ray photoelectron spectroscopy (XPS)

X-ray photoelectron spectroscopy (XPS) are used to determines the surface properties of P25, IM-5wt% Ag/TiO<sub>2</sub>, FSP-TiO<sub>2</sub>, FSP-5wt% Ag/TiO<sub>2</sub> and FSP-7wt% Ag/TiO<sub>2</sub>. The XPS spectra of Ti 2p, O 1s and Ag 3d and the element compositions (%) are shown in figure 40-52 and the percentage of photocatalysts table 7-8. The binding energy of Ti 2p<sub>1/2</sub> and Ti 2p<sub>3/2</sub> were located at about 465 eV and 459 eV respectively. These peaks are according with the valance state of Ti<sup>4+</sup> on lattice oxygen [66, 67, 78] and detect Ti<sup>3+</sup> form on oxygen vacancy [79]. The Ti<sup>3+</sup>/Ti<sup>4+</sup> ratio of FSP-made catalysts was more than P25 and FSP-made catalysts which according to amount of oxygen vacancies. The binding energy of O 1s were located at about 530.7 eV and 532 eV respectively. The valance state of O is lattice oxide ions in TiO<sub>2</sub> and the hydroxyl groups (R-OH) on the TiO<sub>2</sub> surface such as C-OH bond, Ti-OH bond and C=O bond were excited at 532.3 eV, 531.2 eV and 530.2 eV respectively [80]. The binding energy of oxygen bonded with silver (Ag-O) and TiO<sub>2</sub> crystal lattice (Ti-O-Ti) were identified about 529.8 eV [79]. The oxygen vacancies of FSP-made catalysts were more than P25 and FSP-made catalysts which lead to increase the defect on surface of photocatalysts. The binding energy of Ag 3d<sub>5/2</sub> and Ag 3d<sub>3/2</sub> were located at about 368.2 eV and 374.3 eV respectively which show in figure 55. The valance state of Ag is Ag<sup>0</sup>, Ag<sup>1+</sup> and Ag<sup>2+</sup> on lattice oxygen [66, 67, 78] which accord with 368.3 eV, 367.6 eV and 367.05 eV respectively [79]. The silver content in the surface layer of all photocatalysts shows the Ag species in the metallic state [79, 80]. Which confirms the value of crystalline structure from XRD pattern and the morphology from TEM images. The Ti<sup>3+</sup>/Ti<sup>4+</sup> ratio and oxygen vacancies (O<sub>v</sub>) of used FSP-7wt% Ag/TiO<sub>2</sub> photocatalyst were decreased due to the use of recycle to check its stability. Which shows in figure 53-54 and table 10.

## 5.2 Photocatalytic activity

The photocatalytic activity of pure  $\text{TiO}_2$  and all the  $\text{Ag/TiO}_2$  photocatalysts are evaluated by  $\text{CO}_2$  reduction of photocatalyst in water at ambient temperature under UVC irradiation. From our test results, methane ( $\text{CH}_4$ ) is a main product which obtained from all photocatalysts and low amounts of hydrogen ( $\text{H}_2$ ) and carbon monoxide ( $\text{CO}$ ) were also detected. The other products such as formic acid, formaldehyde, ethane and ethylene were undetected [17, 33]. Figure 56 shows the graph between the production yield of  $\text{CH}_4$  from P25 and all IM- $\text{Ag/TiO}_2$  photocatalysts after 3 h reaction. It can be seen that IM-5wt%  $\text{Ag/TiO}_2$  has a greatest effect on the photocatalytic activity among P25 and IM-made photocatalysts. Addition of Ag also promoted the catalytic activity of the photocatalysts. IM-5wt%  $\text{Ag/TiO}_2$  shows the best photocatalytic activity. Moreover, the investigation was exhibited the increasing reaction rate with the increasing of Ag content. IM-7wt%  $\text{Ag/TiO}_2$  exhibited the lower photocatalytic activity when that was compared with IM-5wt%  $\text{Ag/TiO}_2$ . The cause of IM-7wt%  $\text{Ag/TiO}_2$  is due to amount of Ag doped on  $\text{TiO}_2$  which is unsuitable. That may exhibit the electron-hole ( $e^-/h^+$ ) recombination centers. This phenomenon negatively affects the photocatalytic efficiency. Therefore, the suitable Ag doped on  $\text{TiO}_2$  can improve the photocatalytic activity of  $\text{TiO}_2$  support. The yield  $\text{CH}_4$  of IM-5wt%  $\text{Ag/TiO}_2$  photocatalyst exhibits the yield  $\text{CH}_4$  higher than P25 and IM-made photocatalysts which is 0.75  $\mu\text{mol/gcat.h}$  in figure 56. Figure 58 shows the graph production of the yield  $\text{CH}_4$  from FSP- $\text{TiO}_2$  and FSP- $\text{Ag/TiO}_2$  photocatalysts after 3 h reaction. FSP-7wt%  $\text{Ag/TiO}_2$  has the best activity from FSP-made photocatalysts. The FSP- $\text{TiO}_2$  has a badly activity on the yield  $\text{CH}_4$  production compared with FSP- $\text{Ag/TiO}_2$  photocatalysts. FSP-7wt%  $\text{Ag/TiO}_2$  shows the best photocatalytic activity between these. Therefore, this experiment exhibited the increasing reaction rate when increasing Ag content was doped on  $\text{TiO}_2$  support. Figure 55-58 showed the best yield  $\text{CH}_4$  of FSP-7wt%  $\text{Ag/TiO}_2$  photocatalyst higher than FSP-made photocatalysts and all photocatalysts in figure which is 2.22  $\mu\text{mol/gcat.h}$ . Figure 60 shows the graph production yield of  $\text{CH}_4$  from FSP-7wt%  $\text{Ag/TiO}_2$  in varied NaOH concentration. It can be shown that FSP-7wt%  $\text{Ag/TiO}_2$  in DI water has a great effect on the photocatalytic activity which was compared with

0.1M NaOH, 0.2M NaOH and 0.3M NaOH. Figure 61-62 shows the stability of FSP-7wt% Ag/TiO<sub>2</sub>. The yield CH<sub>4</sub> of first round is 2.22  $\mu\text{mol/gcat.h}$  after that second round and third round are decreased to 1.85  $\mu\text{mol/gcat.h}$  and 1.36  $\mu\text{mol/gcat.h}$  respectively as. The cause of this result was shown in figure 53-54 and table 10.

## CHAPTER VI

### CONCLUSION

#### 6.1 Conclusions

Ag/TiO<sub>2</sub> photocatalysts with various amounts of silver (Ag) doping have successfully prepared by using flame spray pyrolysis (FSP) and dry impregnation (IM) method. The XRD pattern of IM-Ag/TiO<sub>2</sub> and FSP-Ag/TiO<sub>2</sub> photocatalysts exhibited only the peaks according to rutile and anatase TiO<sub>2</sub> because of well-dispersed Ag particles on TiO<sub>2</sub> supports, on the other hand, only FSP-7wt% Ag/TiO<sub>2</sub> photocatalysts showed the presence of Ag metal phase. From XPS result, the Ti<sup>3+</sup> and oxygen vacancies of FSP-made photocatalysts was higher than IM-made photocatalysts. The PL spectra confirm the electron-hole recombination rate of all photocatalysts decreased as the increased of Ag doping. From PL results, the recombination rate FSP-made photocatalysts were much less than IM-made photocatalysts. The UV-Vis spectra also revealed that the increased Ag doping content led to improve the ability of absorption at visible light region. The TEM images of IM-made and FSP-made photocatalysts showed the well-dispersion Ag metal on TiO<sub>2</sub> support. From the reaction test, the photocatalytic activity of FSP-made catalysts was higher compare with IM-made one. The CH<sub>4</sub> yield of FSP-7wt% Ag/TiO<sub>2</sub> is highest among all photocatalysts at 2.22  $\mu\text{mol/gCat.h}$ . The higher catalytic activity would be due to the higher of Ti<sup>3+</sup> of FSP-made catalysts. Addition of Ag also promoted the photocatalytic activity due to the Ag can act as electron trap sites, which decreased the electron-hole recombination.

#### 6.2 Recommendation

6.2.1 Investigate the effect of other condition such as light source and other pH of solution

6.2.2 Modify or design a photoreactor that lead to highly photocatalytic reaction

## APPENDIX A

## CALCULATION FOR CATALYST PREPARATION

Table 11: Chemical properties of the catalyst precursor

Chemicals	Molecular weight (g/mole)	Formula	Molecular weight of precursor (g/mole)	Purity (%)
Titanium (IV) isopropoxide	79.87	$Ti\{(OCH(CH_3))_2\}_4$	284.22	97
Silver (I) nitrate	107.87	$Ag(NO_3)$	169.87	99.5
Titanium (II) oxide	79.87	$TiO_2$	79.88	>99

Calculation of mixed metal oxide support prepared by impregnation method

For example:

The calculation for the preparation of Ag doped on  $TiO_2$ , Titanium (II) oxide with silver (I) nitrate as Ag precursor

Base on 100g of catalyst used, the composition of the catalyst will be as follows:

Ag = 1g and Support = 99g

For 2 g of support Ag required =  $2 \times (1/99) = 0.02$  g

thus, Ag 0.02g was prepared from silver (I) nitrate.

$$\text{Ag precursor required} = \frac{0.02 \text{ g Ag}}{107.87 \text{ g/mole Ag}} \times \frac{169.87 \text{ precursor Ag}}{1 \text{ mole Ag}} \times \frac{100}{99.8} = 0.03 \text{ g}$$

Calculation of mixed metal oxide support prepared by flame spray pyrolysis

For example:

The calculation for the preparation of Ag doped on  $TiO_2$ , Titanium (IV) isopropoxide and silver (I) nitrate were used as Ag precursor and then diluted with butanol to a 0.5M solution.

The composition of the catalyst will be as follows:

Ag = 1g and TiO<sub>2</sub> = 99g

$$\text{Conversion to mole fraction Ag} = \frac{1 \text{ g}}{107.87 \text{ g/mole}} = 9.27 \times 10^{-3} \text{ mole Ag}$$

$$\text{TiO}_2 = \frac{99 \text{ g}}{79.87 \text{ g/mole}} = 1.24 \text{ mol TiO}_2$$

$$\therefore \text{Total mole fraction} = (9.27 \times 10^{-3}) + 1.24 = 1.24927 \text{ mole}$$

Basis on 500ml of liquid precursor with 0.5M

$$\text{Ag} = \frac{9.27 \times 10^{-3} \text{ mole Ag}}{1.24927 \text{ mole}} \times 500 \text{ ml} \times \frac{0.5 \text{ mole}}{1000 \text{ ml}} = 0.001855 \text{ mole Ag}$$

$$\text{TiO}_2 = \frac{1.24 \text{ mole TiO}_2}{1.24927 \text{ mole}} \times 500 \text{ ml} \times \frac{0.5 \text{ mole}}{1000 \text{ ml}} = 0.2481 \text{ mole TiO}_2$$

Calculation of usage chemical precursor

$$\text{Ag precursor} = 0.001855 \text{ mole Ag} \times \frac{169.87 \text{ precursor Ag}}{1 \text{ mole Ag}} \times \frac{100}{99.8} = 0.316 \text{ g}$$

$$\text{TiO}_2 \text{ precursor} = 0.2481 \text{ mole TiO}_2 \times \frac{1 \text{ ml}}{0.96 \text{ g/cm}^3} \times \frac{100}{97} = 75.72 \text{ ml}$$

## APPENDIX B

## CALCULATION OF THE CRYSTALLITE SIZE

Calculation of the crystallite size by Debye-Scherrer's equation

The crystallite size was calculated from the half-height width of the diffraction peak of XRD pattern using the Debye-Scherrer's equation.

Figure 63: Derivation of Bragg's law of x-ray diffraction

Bragg's law of x-ray diffraction is  $d = \frac{n\lambda}{2\sin\theta}$

And Scherrer's equation is  $D = \frac{K\lambda}{\beta\cos\theta}$

when  $D$  = Crystallite size, Å

$K$  = Crystallite-shape factor = 0.9

$\lambda$  = X-ray wavelength, 1.5418 Å for  $\text{CuK}\alpha$

$\theta$  = Observes peak angle, degree

$\beta$  = X-ray diffraction broadening, radian

The pure width of powder diffraction free from all broadening owing to the experimental equipment was indicated by X-ray diffraction broadening ( $\beta$ ). A standard sample to observe the influential broadening was indicated by  $\alpha$ -alumina when a crystallite size is larger than 2000Å. Therefore, X-ray diffraction broadening ( $\beta$ ) can be calculated by Warren's formula.

Warren's formula is  $\beta = \sqrt{B_M^2 - B_S^2}$

when  $B_M$  = The measured peak width in radians at half peak height.

$B_S$  = The corresponding width of the standard material.

Figure 64: The determining of FWHM value of XRD line broadening

Figure 65: The plot indicating the value of line broadening owing to instrument. The  $\alpha$ -alumina is a standard for indicated the data.

For example:

Calculation of the crystallite size of P25

Figure 66: The half-height width of P25 at  $25.33^\circ$  as an anatase phase

Crystallite size of anatase  $\text{TiO}_2$ : The half-height width  $= 0.42216^\circ$   
 $= 0.42216 \times \frac{2\pi}{360}$   
 $= 0.007364$  radian

The peak width:  $\beta = \sqrt{0.007364^2 - 0.003836^2}$   
 $= 0.006286$  radian

$$2\theta = 25.33^\circ$$

$$\theta = 12.66^\circ$$

$$\lambda = 1.5418 \text{ \AA}$$

The crystallite sizes:  $D = \frac{K\lambda}{\beta \cos\theta}$   
 $= \frac{0.9 \times 1.5418}{0.006286 \times \cos(12.66)}$   
 $= 221.84 \text{ \AA}$   
 $= 22.18 \text{ nm.}$

Calculation  $\%Anatase = \frac{0.79 \times I_A}{I_R + (0.79 \times I_A)} \times 100$  and

$$\%Rutile = \frac{I_R}{I_R + (0.79 \times I_A)} \times 100$$

When  $I_A$  = The intensity of main anatase peak height at  $2\theta = 25.33^\circ$

$I_R$  = The intensity of main rutile peak height at  $2\theta = 27.42^\circ$

So,  $\%Anatase = \frac{0.79 \times 499.05}{93.73 + (0.79 \times 99.05)} \times 100 = 80.79\%$

$$\%Rutile = \frac{93.73}{93.73 + (0.79 \times 499.05)} \times 100 = 19.21\%$$

## APPENDIX C

CALCULATION OF THE ENERGY BAND GAP ( $E_g$ )

Determination of electronic gap energy of semiconductor by using cut-off wavelength

from spectrum using the following equation:  $E_g = \frac{hc}{\lambda}$

when  $E_g$  = Energy band gap (eV)

$\lambda$  = Wavelength (nm)

$h$  = Planck's constant ( $4.135 \times 10^{-15}$  eV.s)

$c$  = Speed of light ( $3 \times 10^8$  m/s)

For example:

Calculation for photocatalyst absorbed UV irradiation at 350 nm.

$$\text{Energy band gap } (E_g) = \frac{(4.135 \times 10^{-15} \text{ eV} \cdot \text{s}) \times (3 \times 10^8 \frac{\text{m}}{\text{s}})}{350 \text{ nm}} = 3.54 \text{ eV.}$$

Determination of energy band gap by Kubelka-Munk transform reflectance spectra

with  $\left[\frac{F(R_\infty)hc}{\lambda}\right]^2$  versus  $\frac{hc}{\lambda}$  graph

$$\text{Kubelka-Munk function is } F(R_\infty) = \frac{(1-R_\infty)^2}{2R_\infty}$$

when Transform absorbent unit into reflectance  $R_\infty = 10^{-A}$

$R_\infty$  = Reflectance unit

$\lambda$  = Wavelength (nm)

$A$  = absorbent unit

$h$  = Plank constant ( $4.135 \times 10^{-15}$  eV.s)

$c$  = Speed of light ( $3 \times 10^8$  m/s)
